

COMP3040 Lab Session L03 – AsyncTask

Launch Android Studio and follow the usual steps to create a new project, entering *AsyncDemo* into the Application name field and *example.com* as the Company Domain setting before clicking on the Next button.

On the form factors screen, enable the Phone and Tablet option and set the minimum SDK setting to API 19: Android 4.4 (KitKat). Continue to proceed through the screens, requesting the creation of an Empty Activity named *AsyncDemoActivity* using the default for the layout resource files. Click Finish to create the new project.

Load the *activity_async_demo.xml* file for the project into the Layout Editor tool. Select the default TextView component and change the ID for the view to *myTextView* in the Attributes tool window.

With autoconnect mode disabled, add a Button view to the user interface, positioned directly beneath the existing TextView object. Once the button has been added, click on the Infer Constraints button in the toolbar to add the missing constraints.

Change the text to “Press Me” and extract the string to a resource named *press_me*. With the button view still selected in the layout locate the *onClick* property and enter *buttonClick* as the method name.

Next, load the *AsyncDemoActivity.java* file into an editing panel and add code to implement the *buttonClick()* method which will be called when the Button view is touched by the user. Since the goal here is to demonstrate the problem of performing lengthy tasks on the main thread, the code will simply pause for 20 seconds before displaying different text on the TextView object:

```

package com.example.asyncdemo;

import android.support.v7.app.AppCompatActivity;
import android.os.Bundle;
import android.view.View;
import android.widget.TextView;

public class AsyncDemoActivity extends AppCompatActivity {

    private TextView myTextView;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_async_demo);

        myTextView =
            (TextView) findViewById(R.id.myTextView);

        public void buttonClick(View view) {
            int i = 0;
            while (i <= 20) {
                try {
                    Thread.sleep(1000);
                    i++;
                }
                catch (Exception e) {
                }
            }
            myTextView.setText("Button Pressed");
        }
    }
}

```

With the code changes complete, run the application on either a physical device or an emulator. Once the application is running, touch the Button, at which point the application will appear to freeze. It will, for example, not be possible to touch the button a second time and in some situations the operating system will report the application as being unresponsive:

Clearly, anything that is going to take time to complete within the `buttonClick()` method needs to be performed within a separate thread.

In order to create a new thread, the code to be executed in that thread needs to be performed within an AsyncTask instance. The first step is to subclass AsyncTask in the AsyncDemoActivity.java file as follows:

```
..
import android.os.AsyncTask;

public class AsyncDemoActivity extends AppCompatActivity {

    ..
    private class MyTask extends AsyncTask<String, Void, String> {

        @Override
        protected void onPreExecute() {
        }

        @Override
        protected String doInBackground(String... params) {
        }

        @Override
        protected void onProgressUpdate(Void... values) {
        }

        @Override
        protected void onPostExecute(String result) {
        }
    }
    ..
}
```

The AsyncTask class uses three different types which are declared in the class signature line as follows:

```
private class MyTask extends AsyncTask<Type1, Type2, Type3> {
    ..
}
```

These three types correspond to the argument types for the doInBackground(), onProgressUpdate() and onPostExecute() methods respectively. If a method does not expect an argument then Void is used, as is the case for the onProgressUpdate() in the above code. To change the argument type for a method, change the type declaration both in the class declaration and in the method signature. For this example, the onProgressUpdate() method will be passed an Integer, so modify the class declaration as follows:

```
private class MyTask extends AsyncTask<String, Integer, String> {

    ..
    @Override
    protected void onProgressUpdate(Integer... values) {
    }
    ..
}
```

The `onPreExecute()` is called before the background tasks are initiated and can be used to perform initialization steps. This method runs on the main thread so may be used to update the user interface.

The code to be performed in the background on a different thread from the main thread resides in the `doInBackground()` method. This method does not have access to the main thread so cannot make user interface changes. The `onProgressUpdate()` method, however, is called each time a call is made to the `publishProgress()` method from within the `doInBackground()` method and can be used to update the user interface with progress information.

The `onPostExecute()` method is called when the tasks performed within the `doInBackground()` method complete. This method is passed the value returned by the `doInBackground()` method and runs within the main thread allowing user interface updates to be made.

Modify the code to move the timer code from the `buttonClick()` method to the `doInBackground()` method as follows:

```
@Override
protected String doInBackground(String... params) {
    int i = 0;
    while (i <= 20) {
        try {
            Thread.sleep(1000);
            publishProgress(i);
            i++;
        }
        catch (Exception e) {
            return(e.getLocalizedMessage());
        }
    }
    return "Button Pressed";
}
```

Next, move the `TextView` update code to the `onPostExecute()` method where it will display the text returned by the `doInBackground()` method:

```
@Override
protected void onPostExecute(String result) {
    myTextView.setText(result);
}
```

To provide regular updates via the `onProgressUpdate()` method, modify the class to add a call to the `publishProgress()` method in the timer loop code (passing through the current loop counter) and to display the current count value in the `onProgressUpdate()` method:

```

@Override
protected String doInBackground(String... params) {
    int i = 0;
    while (i <= 20) {
        publishProgress(i);
        try {
            Thread.sleep(1000);
            publishProgress(i);
            i++;
        }
        catch (Exception e) {
            return(e.getLocalizedMessage());
        }
    }
    return "Button Pressed";
}

@Override
protected void onProgressUpdate(Void... values) {
    myTextView.setText("Counter = " + values[0]);
}

```

Finally, modify the `buttonClicked()` method to begin the asynchronous task execution:

```

public void buttonClick(View view) {
    AsyncTask task = new MyTask().execute();
}

```

By default, asynchronous tasks are performed serially. In other words, if an app executes more than one task, only the first task begins execution. The remaining tasks are placed in a queue and executed in sequence as each one finishes. To execute asynchronous tasks in parallel, those tasks must be executed using the `AsyncTask` thread pool executor as follows:

```

AsyncTask task = new
    MyTask().executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR);

```

The number of tasks that can be executed in parallel using this approach is limited by the core pool size on the device which, in turn, is dictated by the number of CPU cores available. The number of CPU cores available on a device can be identified from with app using the following code:

```

int cpu_cores = Runtime.getRuntime().availableProcessors();

```

Android uses an algorithm to calculate the default number of pool threads. The minimum number of threads is 2 while the maximum default value is equal to either 4, or the number of CPU core count minus 1 (whichever is smallest). The maximum possible number of threads available to the pool on any device is calculated by doubling the CPU core count and adding one.

When the application is now run, touching the button causes the delay to be performed in a new thread leaving the main thread to continue handling the user interface, including responding to additional button presses. During the delay, the user interface will be updated every second showing the counter value. On completion of the timeout, the TextView will display the "Button Pressed" message.

A running task may be canceled by calling the `cancel()` method of the task object passing through a Boolean value indicating whether the task can be interrupted before the in-progress task completes:

```
AsyncTask task = new MyTask().execute();  
..  
task.cancel(true);
```

The goal of this exercise was to provide an overview of threading within Android applications. When an application is first launched in a process, the runtime system creates a main thread in which all subsequently launched application components run by default. The primary role of the main thread is to handle the user interface, so any time consuming tasks performed in that thread will give the appearance that the application has locked up. It is essential, therefore, that tasks likely to take time to complete be started in a separate thread.

Because the Android user interface toolkit is not thread-safe, changes to the user interface should not be made in any thread other than the main thread. Background tasks may be performed in separate thread by subclassing the `AsyncTask` class and implementing the class methods to perform the task and update the user interface.
